Wegener's theory of continental drift states that the existing continents of the earth were once glued together forming a super landmass. Over time, the landmass broke and drifted away and is still drifting to this day. In his proposal, he stated that the super continent, which he named Pangaea, meaning "all earth" once existed.

The theory of continental drift is most associated with the scientist Alfred Wegener. In the early 20th century, Wegener published a paper explaining his theory that the continental landmasses were "drifting" across the Earth, sometimes plowing through oceans and into each other. He called this movement continental drift.

Continental Drift Theory According to the theory of continental drift, the world was made up of a single continent (pangaea) through most of geologic time. the continent Pangaea eventually separated and drifted apart, forming into the seven continents. The first theory of continental drift was suggested by the German meteorologist Alfred wegner in 1912.

The theory deals with the distribution of the oceans and the continents. According to Wegener's Continental Drift theory, all the continents were one single continental mass (called a Super Continent) – Pangaea and a Mega Ocean surrounded this supercontinent. The mega ocean is known by the name Panthalassa.

Continental drift was a revolutionary scientific theory developed in the years 1908-1912 by Alfred Wegener (1880-1930), a German meteorologist, climatologist, and geophysicist, that put forth the hypothesis that the continents had all originally been a part of one enormous landmass or supercontinent about 240 million years ago before breaking apart and drifting to their current locations. Based on the work of previous scientists who had theorized about horizontal movement of the continents ...

What Is Continental Drift Theory? - ThoughtCo

Continental drift is the hypothesis that the Earth's continents have moved over geologic time relative to each other, thus appearing to have "drifted" across the ocean bed. The speculation that continents might have "drifted" was first put forward by Abraham Ortelius in 1596. The concept was independently and more fully developed by Alfred Wegener in 1912, but his hypothesis was rejected by many for lack of any motive mechanism. Arthur Holmes later proposed mantle convection for that mechanism.

In the second half of the twentieth century, more evidence emerged that supported the theory of continental drift. This included: • the discovery of mid-oceanic ridges discovered as the result of ocean floor mapping. A mid–ocean ridge or mid–oceanic ridge is an underwater mountain range, formed by plate tectonics. As plates move apart magma rises along the constructive plate margin forming new land along the boundary of the plates;
