An ultrasonic motor is a type of electric motor powered by the ultrasonic vibration of a component, the stator, placed against another component, the rotor or slider depending on the scheme of operation. Ultrasonic motors differ from piezoelectric actuators in several ways, though both typically use some form of piezoelectric material, most often lead zirconate titanate and occasionally lithium niobate or other single-crystal materials. The most obvious difference is the use of resonance to ampl

Piezoelectric Ultrasonic Motor Technology Working and Applications. Ultrasonic motors were invented in 1965 by V.V Lavrinko. In general we are aware of the fact that the motive force is given by the electromagnetic field in the conventional motors. But, here to provide a motive force, these motors utilize the piezoelectric effect in the ultrasonic frequency range, which is from 20 kHz to 10 MHz and is not audible to normal human beings.

Piezoelectric Ultrasonic Motor Technology and Applications

An ultrasonic motor is a piezoelectric device which produces rotary or linear motion from ultrasonic vibrations via friction. Ultrasonic motors produce a much larger torque/force than conventional electromagnetic motors. Several basic principles are introduced for rotary and linear motors.

Ultrasonic motors can be classified into contact and non-contact motor. The contact ultrasonic motors, which consists of a stator and a rotor, are based on the concept of driving the rotor by the frictional contact force between the stator and rotor, as shown in Fig. 1(a). In the past decades, due to its well-recognised benefits, the working mechanism and performance of the contact ultrasonic motors with different structures have been studied.

Ultrasonic motors also offer arbitrarily large rotation or sliding distances, while piezoelectric actuators are limited by the static strain that may be induced in the piezoelectric element. One common application of ultrasonic motors is in camera lenses where they are used to move lens elements as part of the auto-focus system.

Abstract. This study applied appropriate assumptions to simplify a surface acoustic wave (SAW) motor model, as well as the elastic friction layer concept to analyze the two-dimensional contact problem. The effect of inertial force was factored into the equation of motion for the friction layer; the relationship between external force and the displacement of the friction layer surface was determined via Fourier transform; and the displacement field under different loads was analyzed using ...
